Theorem: The Halting Problem is Turing-unsolvable.

...

We assume an encoding of TMs that permits identification of each with some $m \in \mathbb{Z}^+$, and say that the binary halt function h maps a machine and its input to 1 if that machine halts, and to 2 if it doesn't:

$$h(m, n) = 1 \text{ if } m : n \longrightarrow \text{halt}$$

$$h(m, n) = 2 \text{ if } m : n \longrightarrow \infty$$

So, the theorem we need can be expressed this way:

$$\neg \exists m_h [m_h \text{ computes } h]$$

Next, let's construct a TM m_c that copies a block of 1's (separated by a blank #), and (what BBJ call) a "dithering" TM:

$$m_d : n \longrightarrow \text{halt if } n > 1; m_d : n \longrightarrow \infty \text{ if } n = 1$$

Proof: Suppose for *reductio* that m_h computes h . Then we can make a composite machine m^3 consisting of m_c connected to and feeding m_h and this machine connected to and feeding m_d . It's easy to see (use some paper and pencil/stylus and tablet!) that

(1) if $h(n, n) = 1$, then $m^3 : n \longrightarrow \infty$

and

(2) if $h(n, n) = 2$, then $m^3 : n \longrightarrow \text{halt}$.

To reach our desired contradiction, we simply ask: What happens when we instantiate n to m^3 in (1) and (2)? The answer to this question, and its being just what the doctor ordered, is left to the reader. **QED**

Church's Theorem & its proof ...

Theorem: The *Entscheidungsproblem* is Turing-unsolvable.

Proof-sketch: We need to show that the question $\Phi \vdash \phi?$ is not Turing-decidable. (Here we are working within the framework of \mathcal{L}_1 .) To begin, note that competent users of HS[®] know that any Turing machine m can be formalized in a HS[®] workspace. (Explore! Prove it to yourself in hands-on fashion!) They will also then know that

$$(\dagger) \quad \forall m, n \exists \Phi, \phi [\Phi \vdash \phi \leftrightarrow m : n \longrightarrow \text{halt}]$$

where Φ and ϕ are built in HS[®].

Now, let's assume for contradiction that theoremhood in first-order logic can be decided by a Turing machine m_t . But this is absurd. Why? Because imagine that someone now comes to us asking whether some arbitrary TM m halts. We can infallibly supply an answer, because we can formalize m in line with (†) and then employ m_t to give us the answer. **QED**
