Background Context ...

Gödelian Essays on Artificial vs. Human Intelligence: Pretenders vs. Persons

by Selmer Bringsjord • Naveen Sundar Govindarajulu • Alexander Bringsjord

- Introduction (“The Wager”)
- Brief Preliminaries (e.g. the propositional calculus & FOL)
- The Completeness Theorem
- The First Incompleteness Theorem
- The Second Incompleteness Theorem
- The Speedup Theorem
- The Continuum-Hypothesis Theorem
- The Time-Travel Theorem
- Gödel’s “God Theorem”
- Could a Finite Machine Match Gödel’s Greatness?

STOP & REVIEW IF NEEDED!

Gödel Numbering, the Easy Way

Just realize that every entry in a dictionary is named by a number n , and by the same basic lexicographic ordering, every computer program, formula, etc. is named by a number m in a lexicographic ordering going from 1, to 2, to ...

So, gimcrack is named by some positive integer k . Hence, I can just refer to this word as “ k ” Or in the notation I prefer: k^{gimcrack} .

Gödel Numbering, the Easy Way

Just realize that every entry in a dictionary is named by a number n , and by the same basic lexicographic ordering, every computer program, formula, etc. is named by a number m in a lexicographic ordering going from 1, to 2, to ...

Gödel Numbering, the Easy Way

Just realize that every entry in a dictionary is named by a number n , and by the same basic lexicographic ordering, every computer program, formula, etc. is named by a number m in a lexicographic ordering going from 1, to 2, to ...

Or, every syntactically valid computer program in Clojure that you will ever write can be uniquely denoted by some number m in the lexicographic ordering of all syntactically valid such programs. So your program π can just be coded as a numeral m^π in a formal language that captures arithmetic (i.e., an *arithmetic language*).

Gödel's First Incompleteness Theorem

Let Φ be a set of arithmetic sentences that is

- (i) consistent (i.e. no contradiction $\phi \wedge \neg\phi$ can be deduced from Φ);
- (ii) s.t. an algorithm is available to decide whether or not a given string u is a member of Φ ; and
- (iii) sufficiently expressive to logicize all of the operations of a standard computing machine (e.g. a Turing machine, register machine, KU machine, etc.).

Then there is an “undecidable” arithmetic sentence \mathcal{G} from Gödel that can't be proved from Φ , nor can the negation of this sentence (i.e. $\neg\mathcal{G}$) be proved from Φ !

Alas, that's painfully verbose.

Gödel's First Incompleteness Theorem

pocket theorem

Gödel's First Incompleteness Theorem

pocket theorem

Suppose $\Phi \supseteq \mathbf{PA}$ ($= \Phi$ contains \mathbf{PA}) is

- (i) Φ is *consistent*: no contradiction $\phi \wedge \neg\phi$ can be proved from Φ (Con Φ);
- (ii) Membership of strings in Φ is *algorithmically decidable*; and
- (iii) Φ has *capturability*: it can capture functions and relations over \mathbb{N} (Cap Φ).

Then there is a sentence \mathcal{G} s.t. $\Phi \not\vdash \mathcal{G}$ and $\Phi \not\vdash \neg\mathcal{G}$. (\mathcal{G} is an “undecidable” sentence.)

Gödel's First Incompleteness Theorem

To prove G I, we shall
allow ourselves ...

The Fixed Point Theorem (FPT)

“The Self-Ascription Theorem” (GSAT)

Assume that Φ is a set of arithmetic sentences such that $\text{Cap } \Phi$. Then for every arithmetic formula $\psi(x)$ with one free variable x , there is an arithmetic sentence ϕ s.t.

$$\Phi \vdash \phi \leftrightarrow \psi(\hat{n}^\phi).$$

We can intuitively understand ϕ to be saying:

“I have the property ascribed to me by the formula ψ .”

“*I heard there was no free lunch!*”

[W]e “would hope that such a deep theorem would have an insightful proof. No such luck. I am going to write down a sentence ... and verify that it works. What I won’t do is give you a satisfactory explanation for why I write down the particular formula that I do. I write down the formula because Gödel wrote down the formula, and Gödel wrote down the formula because, when he played the logic game he was able to see seven or eight moves ahead, whereas you and I are only able to see one or two moves ahead. I don’t know anyone who thinks he has a fully satisfying understanding of why the Self-referential Lemma [= FPT] works. It has a rabbit-out-of-a-hat quality for everyone.”

—V. McGee, 2002; as quoted in (Salehi 2020)

The Fixed Point Theorem (FPT)

“The Self-Ascription Template Theorem”

Assume that Φ is a set of arithmetic sentences such that $\text{Cap } \Phi$. Then for every arithmetic formula $\psi(x)$ with one free variable x , there is an arithmetic sentence ϕ s.t.

$$\Phi \vdash \phi \leftrightarrow \psi(\hat{n}^\phi).$$

We can intuitively understand ϕ to be saying:

“I have the property ascribed to me by the formula ψ .”

Ok; so let's do it ...

Proof: Let Φ be a set of arithmetic sentences that's a superset of **PA**, and suppose the antecedent of GI holds, i.e. (i)–(iii) hold. We must show that there exists an arithmetic sentence s.t. neither it nor its negation can be proved from Φ . In homage to Gödel, we label this sentence ' \mathcal{G} .'

For *reductio*, assume the opposite: that for every arithmetic sentence ϕ , either $\Phi \vdash \phi$ or $\Phi \vdash \neg\phi$.

Next, let's use the formula $\pi(v)$ to capture provability in Φ , where the variable v is a placeholder ready to receive the Gödel numeral \hat{n}^ϕ of a formula ϕ that's proved. We thus have:

$$(GI.1) \quad \Phi \vdash \pi(\hat{n}^\phi) \text{ iff } \Phi \vdash \phi.$$

Now we bring on stage Gödel's self-ascribing sentence \mathcal{G} , via his Self-Ascription Template Theorem (SATL); specifically, we have:

$$(GI.2) \quad \Phi \vdash \mathcal{G} \leftrightarrow \neg\pi(\hat{n}^\mathcal{G}).$$

"I'm not
provable
from Φ !"

We have two cases to consider, just like what we did in the original Liar Paradox. The first is that \mathcal{G} is provable from Φ ; suppose this holds. Then from (1) right-to-left, and *modus ponens* = conditional elim., with left-to-right (by biconditional elimination) on (3) — contradiction!

How about the second case, viz. that $\Phi \vdash \neg\mathcal{G}$? With this and (3) by *modus tollens* and simplification of a double negation we deduce $\Phi \vdash \pi(\hat{n}^\mathcal{G})$, which with (1) by biconditional elimination yields $\Phi \vdash \mathcal{G}$ — contradiction!, which is ruled out by the assumption that Φ is consistent. **QED**

“Silly abstract nonsense! There aren’t any concrete examples of \mathcal{G} !”
